## On peri-implantitis and implant surfaces

**Abstract** Novel moderately roughened oral implant surfaces have meant a clear increase of implant survival rates than older machined or plasma sprayed surfaces. There is no evidence of any increased levels of peri-implantitis seen to moderately rough surfaces. Dangerous marginal bone loss may start as a complication to treatment and, if continuous, may result in activation of the immune system leading to implant rejection. The role of bacteria is not that clear, but it is certainly possible that bacteria worsen the condition and may combine with the immunologically derived bone loss. Implants are not teeth and they do not follow the same laws as teeth.

Prof. Tomas Albrektsson belonged to Brånemark's original team behind osseointegration and Albrektsson has today worked more than 50 years in the fields of oral, craniofacial and orthopaedic implants. Current research activities are focussed on reasons for marginal bone loss around oral and orthopaedic implants and on the background to implant failure.

DONDERDAG 19 APRIL 2018 – VAN DER VALK HOTEL UTRECHT
